

Cascading Style Sheets[™] (CSS)

Objectives

- To control the appearance of a Web site by creating style sheets.
- To use a style sheet to give all the pages of a Web site the same look and feel.
- To use the class attribute to apply styles.
- To specify the precise font, size, color and other properties of displayed text.
- To specify element backgrounds and colors.
- To understand the box model and how to control the margins, borders and padding.
- To use style sheets to separate presentation from content.

Fashions fade, style is eternal. Yves Saint Laurent

A style does not go out of style as long as it adapts itself to its period. When there is an incompatibility between the style and a certain state of mind, it is never the style that triumphs. Coco Chanel

How liberating to work in the margins, outside a central perception. Don DeLillo

I've gradually risen from lower-class background to lowerclass foreground. Marvin Cohen

6.1 Introduction

In Chapters 4 and 5, we introduced the Extensible HyperText Markup Language (XHTML) for marking up information. In this chapter, we shift our focus to formatting and presenting information. To do this, we use a W3C technology called **Cascading Style Sheets** (**CSS**) that allows document authors to specify the presentation of elements on a Web page (e.g., fonts, spacing, margins, etc.) separately from the structure of the document (section headers, body text, links, etc.). This **separation of structure from presentation** simplifies maintaining and modifying a document's layout.

6.2 Inline Styles

A Web developer can declare document styles in many ways. This section presents **inline styles** that declare an individual element's format using the XHTML attribute **style**. Inline styles override any other styles applied using the techniques we discuss later in the chapter. Figure 6.1 applies inline styles to p elements to alter their font size and color.

```
1
    <?xml version = "1.0"?>
2
    <!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1//EN"
 3
       "http://www.w3.org/TR/xhtml11/DTD/xhtml11.dtd">

         25
         This text has the <em>font-size</em> and
26
         <em>color</em> styles applied to it, making it
27
         20pt. and blue.
28
29
      </body>
30
    </html>
```

Fig. 6.1 Inline styles. (Part 2 of 2.)

The first inline style declaration appears in line 20. Attribute style specifies the style for an element. Each **CSS property** (the **font-size** property in this case) is followed by a colon and a value. In line 20, we declare this particular p element to use 20-point font size. Line 21 uses element **em** to "emphasize" text, which most browsers do by making the font italic.

Line 24 specifies the two properties, font-size and **color**, separated by a semicolon. In this line, we set the given paragraph's color to blue, using the hexadecimal code #0000ff. Color names may be used in place of hexadecimal codes, as we demonstrate in the next example. We provide a list of hexadecimal color codes and color names in Appendix B.

6.3 Embedded Style Sheets

A second technique for using style sheets is **embedded style sheets**. Embedded style sheets enable a Web-page author to embed an entire CSS document in an XHTML document's head section. Figure 6.2 creates an embedded style sheet containing four styles.

```
<?xml version = "1.0"?>
 1
2
    <!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1//EN"

```

Fig. 6.2 Embedded style sheets. (Part 2 of 2.)

The style element (lines 13–24) defines the embedded style sheet. Styles placed in the head apply to matching elements wherever they appear in the entire document. The style element's type attribute specifies the Multipurpose Internet Mail Extensions (MIME) type that describes a file's content. CSS documents use the MIME type text/css. Other MIME types include image/gif (for GIF images) and text/javascript (for the JavaScript scripting language, which we discuss in Chapters 7–12).

The body of the style sheet (lines 15-22) declares the **CSS rules** for the style sheet. We declare rules for em (lines 15-16), h1 (line 18) and p (line 20) elements. When the browser renders this document, it applies the properties defined in these rules to every element to which the rule applies. For example, the rule in lines 15-16 will be applied to all em elements (in this example, there is one in line 43). The body of each rule is enclosed in curly braces ({ and }).

Line 22 declares a **style class** named **special**. Style classes define styles that can be applied to any type of element. In this example, we declare class **special**, which sets **color** to **blue**. We can apply this style to elements of any type, whereas the other rules in

this style sheet apply only to specific element types (i.e., em, h1 or p). Style class declarations are preceded by a period. We will discuss how to apply a style class momentarily.

CSS rules in embedded style sheets use the same syntax as inline styles; the property name is followed by a colon (:) and the value of the property. Multiple properties are separated by semicolons (;). In the rule for em elements, the color property specifies the color of the text, and property **background-color** specifies the background color of the element.

The **font-family** property (line 18) specifies the name of the font to use. In this case, we use the arial font. The second value, sans-serif, is a generic font family. Not all users have the same fonts installed on their computers, so Web-page authors often specify a comma-separated list of fonts to use for a particular style. The browser attempts to use the fonts in the order they appear in the list. Many Web-page authors end a font list with a generic font family name in case the other fonts are not installed on the user's computer. In this example, if the arial font is not found on the system, the browser instead will display a generic sans-serif font, such as helvetica or verdana. Other generic font families include serif (e.g., times new roman, Georgia), cursive (e.g., script), fantasy (e.g., critter) and monospace (e.g., courier, fixedsys).

The **font-size** property (line 20) specifies a 14-point font. Other possible measurements in addition to **pt** (point) are introduced later in the chapter. Relative values— **xxsmall**, **x-small**, **small**, **smaller**, **medium**, **large**, **larger**, **x-large** and **xx-large** also can be used. Generally, relative values for **font-size** are preferred over point sizes because an author does not know the specific measurements of the display for each client. Relative **font-size** values permit more flexible viewing of Web pages. For example, a user may wish to view a Web page on a handheld device with a small screen. Specifying an 18point font size in a style sheet will prevent such a user from seeing more than one or two characters at a time. However, if a relative font size is specified, such as large or larger, the actual size is determined by the browser that displays the font. Using relative sizes also makes pages more accessible to users with disabilities. Users with impaired vision, for example, may configure their browser to use a larger default font, upon which all relative sizes are based. Text that the author specifies to be smaller than the main text still displays in a smaller size font, yet it is clearly visible to each user.

Line 30 uses attribute **class** in an h1 element to apply a style class—in this case class special (declared as .special in the style sheet). When the browser renders the h1 element, note that the text appears on screen with the properties of both an h1 element (arial or sans-serif font defined in line 18) and the .special style class applied (the color blue defined in line 22).

The formatting for the p element and the .special class are applied to the text in lines 42–49. All the styles applied to an element (the **parent** or **ancestor element**) also apply to the element's nested elements (**child** or **descendant elements**). The em element nested in the p element in line 43 **inherits** the style from the p element (namely, the 14-point font size in line 20), but retains its italic style. The em element has its own color property, so it overrides the color property of the special class. We discuss the rules for resolving these conflicts in the next section.

6.4 Conflicting Styles

Cascading style sheets are "cascading" because styles may be defined by a user, an author or a **user agent** (e.g., a Web browser). Styles "cascade," or flow together, such that the ul-

timate appearance of elements on a page results from combining styles defined in several ways. Styles defined by the user take precedence over styles defined by the user agent, and styles defined by authors take precedence over styles defined by the user. Styles defined for parent elements are also inherited by child (nested) elements. In this section, we discuss the rules for resolving conflicts between styles defined for elements and styles inherited from parent and ancestor elements.

Figure 6.2 presented an example of **inheritance** in which a child em element inherited the font-size property from its parent p element. However, in Fig. 6.2, the child em element had a color property that conflicted with (i.e., had a different value than) the color property of its parent p element. Properties defined for child and descendant elements have a greater **specificity** than properties defined for parent and ancestor elements. According to the W3C CSS Recommendation, conflicts are resolved in favor of properties with a higher specificity. In other words, the styles explicitly defined for a child element are more specific than the styles defined for the child's parent element; therefore, the child's styles take precedence. Figure 6.3 illustrates examples of inheritance and specificity.

34
```

Fig. 6.3 Inheritance in style sheets. (Part 2 of 2.)

Line 14 applies property text-decoration to all a elements whose class attribute is set to nodec. The text-decoration property applies decorations to text within an

element. By default, browsers underline the text of an a (anchor) element. Here, we set the text-decoration property to none to indicate that the browser should not underline hyperlinks. Other possible values for text-decoration include **overline**, **line-through**, **underline** and **blink**. [*Note*: blink is not supported by Internet Explorer.] The .nodec appended to a is an extension of class styles; this style will apply only to a elements that specify nodec in their class attribute.

Portability Tip 6.1

To ensure that your style sheets work in various Web browsers, test them on all the client Web browsers that will render documents using your styles.

Lines 16–18 specify a style for hover, which is a **pseudoclass**. Pseudoclasses give the author access to content not specifically declared in the document. The hover pseudoclass is activated dynamically when the user moves the mouse cursor over an element. Note that pseudoclasses are separated by a colon (with no surrounding spaces) from the name of the element to which they are applied.

Common Programming Error 6.1

Including a space before or after the colon separating a pseudoclass from the name of the element to which it is applied is an error that prevents the pseudoclass from being applied properly.

Lines 20–21 declare a style for all em elements that are children of li elements. In the screen output of Fig. 6.3, note that **Monday** (which line 33 contains in an em element) does not appear in bold red, because the em element is not in an li element. However, the em element containing with mushrooms (line 46) is nested in an li element; therefore, it is formatted in bold red.

The syntax for applying rules to multiple elements is similar. For example, to apply the rule in lines 20–21 to all li and em elements, you would separate the elements with commas, as follows:

li, em { color: red; font-weight: bold }

Lines 25–26 specify that all nested lists (ul elements that are descendants of ul elements) are to be underlined and have a left-hand margin of 15 pixels. A pixel is a **relative-length measurement**—it varies in size, based on screen resolution. Other relative lengths are **em** (the so-called *M*-height of the font, which is usually set to the height of an uppercase *M*), **ex** (the so-called *x*-height of the font, which is usually set to the height of a lowercase *x*) and percentages (e.g., margin-left: 10%). To set an element to display text at 150% of its default text size, the author could use the syntax

font-size: 1.5em

Other units of measurement available in CSS are **absolute-length measurements**—i.e., units that do not vary in size based on the system. These units are **in** (inches), **cm** (centimeters), **mm** (millimeters), **pt** (points; 1 pt=1/72 in) and **pc** (picas—1 pc = 12 pt).

Good Programming Practice 6.1

Whenever possible, use relative-length measurements. If you use absolute-length measurements, your document may not be readable on some client browsers (e.g., wireless phones). In Fig. 6.3, the entire list is indented because of the 75-pixel left-hand margin for toplevel ul elements. However, the nested list is indented only 15 pixels more (not another 75 pixels) because the child ul element's margin-left property (in the ul ul rule in line 25) overrides the parent ul element's margin-left property.

6.5 Linking External Style Sheets

Style sheets are a convenient way to create a document with a uniform theme. With **external style sheets** (i.e., separate documents that contain only CSS rules), Web-page authors can provide a uniform look and feel to an entire Web site. Different pages on a site can all use the same style sheet. When changes to the styles are required, the Web-page author needs to modify only a single CSS file to make style changes across the entire Web site. Figure 6.4 presents an external style sheet. Lines 1–2 are **CSS comments**. Like XHTML comments, CSS comments describe the content of a CSS document. Comments may be placed in any type of CSS code (i.e., inline styles, embedded style sheets and external style sheets) and always start with /* and end with */. Text between these delimiters is ignored by the browser.

```
1
                                */
    /* Fig. 6.4: styles.css
2
    /* An external stylesheet */
3
4
    а
             { text-decoration: none }
5
6
    a:hover { text-decoration: underline;
7
               color: red;
8
               background-color: #ccffcc }
9
10
    li em
             { color: red;
11
               font-weight: bold;
12
               background-color: #ffffff }
13
14
             { margin-left: 2cm }
    u1
15
16
             { text-decoration: underline;
    ul ul
17
               margin-left: .5cm }
```

Fig. 6.4 External style sheet (styles.css).

Figure 6.5 contains an XHTML document that references the external style sheet in Fig. 6.4. Lines 11–12 (Fig. 6.5) show a **link** element that uses the **rel** attribute to specify a **relationship** between the current document and another document. In this case, we declare

```
1 <?xml version = "1.0"?>
2 <!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1//EN"
3 "http://www.w3.org/TR/xhtml11/DTD/xhtml11.dtd">

       </body>
37
    </html>
```

Fig. 6.5 Linking an external style sheet. (Part 3 of 3.)

the linked document to be a **stylesheet** for this document. The type attribute specifies the MIME type as text/css. The href attribute provides the URL for the document containing the style sheet. In this case, styles.css is in the same directory as external.html.

Software Engineering Observation 6.1

External style sheets are reusable. Creating them once and reusing them reduces programming effort.

Software Engineering Observation 6.2

The link element can be placed only in the head element. The user can specify next and previous as values of the rel attribute, which allow the user to link a whole series of documents. This feature allows browsers to print a large collection of related documents at once. (In Internet Explorer, select **Print all linked documents** in the **Print...** submenu of the **File** menu.)

6.6 W3C CSS Validation Service

The W3C provides a validation service (jigsaw.w3.org/css-validator) that validates external CSS documents to ensure that they conform to the W3C CSS Recommendation. Like XHTML validation, CSS validation ensures that style sheets are syntactically correct. The validator provides the option of either entering the CSS document's URL, pasting the CSS document's contents into a text area or uploading a CSS document.

Figure 6.6 illustrates uploading a CSS document, using the file upload feature available at jigsaw.w3.org/css-validator/validator-upload.html.

To validate the document, click the **Browse...** button to locate the file on your computer. Like many W3C Recommendations, the CSS Recommendation is being developed in stages (or versions). The current version under development is Version 3, so select **CSS** version 3 in the **Profile** drop-down list. This field indicates to the validator the CSS Recommendation against which the uploaded file should be validated. Click **Submit this CSS** **file for validation** to upload the file for validation. Figure 6.7 shows the results of validating styles.css (Fig. 6.4).

6.7 Positioning Elements

Before CSS, controlling the positioning of elements in an XHTML document was difficult—the browser determined positioning. CSS introduced the **position** property and a capability called **absolute positioning**, which gives authors greater control over how document elements are displayed. Figure 6.8 demonstrates absolute positioning.

```
1
    <?xml version = "1.0"?>
2

22
            "Second positioned image" />
23
24
       </body>
25
    </html>
```

Lines 15–17 position the first img element (i.gif) on the page. Specifying an element's position as **absolute** removes the element from the normal flow of elements on the page, instead positioning it according to the distance from the top, left, right or bottom margins of its **containing block-level element** (i.e., an element such as body or p). Here, we position the element to be 0 pixels away from both the top and left margins of the p element (lines 15–17).

The **z-index** attribute allows you to layer overlapping elements properly. Elements that have higher z-index values are displayed in front of elements with lower z-index values. In this example, i.gif has the lowest z-index (1), so it displays in the background. The img element in lines 20–22 (circle.gif) has a z-index of 2, so it displays in front of i.gif. The p element in lines 18–19 (Positioned Text) has a z-index of 3, so it displays in front of the other two. If you do not specify a z-index or if elements have the same z-index value, the elements are placed from background to foreground in the order they are encountered in the document.

Absolute positioning is not the only way to specify page layout. Figure 6.9 demonstrates **relative positioning**, in which elements are positioned relative to other elements.

Fig. 6.9 Relative positioning of elements with CSS. (Part 2 of 2.)

Setting the position property to relative, as in class super (lines 21-22), lays out the element on the page and offsets it by the specified top, bottom, left or right value. Unlike absolute positioning, relative positioning keeps elements in the general flow of elements on the page, so positioning is relative to other elements in the flow. Recall that ex (line 22) is the x-height of a font, a relative length measurement typically equal to the height of a lowercase x.

We introduce the **span** element in line 39. Element **span** is a **grouping element**—it does not apply any inherent formatting to its contents. Its primary purpose is to apply CSS rules or id attributes to a block of text. Element **span** is an **inline-level element**—it is displayed inline with other text and with no line breaks. Lines 17–19 define the CSS rule for **span**. A similar element is the **div** element, which also applies no inherent styles but is displayed on its own line, with margins above and below (a block-level element).

Bec to

Common Programming Error 6.2

Because relative positioning keeps elements in the flow of text in your documents, be careful to avoid unintentionally overlapping text.

6.8 Backgrounds

CSS provides control over the element backgrounds. In previous examples, we introduced the background-color property. CSS also can add background images to documents. Figure 6.10 adds a corporate logo to the bottom-right corner of the document. This logo stays fixed in the corner even when the user scrolls up or down the screen.

36
           right corner of the page. Notice how the logo
37
           stays in the proper position when you resize the
38
           browser window.
39
           40
```

Fig. 6.10 Background image added with CSS. (Part 2 of 2.)

The **background-image** property (line 14) specifies the image URL for the image logo.gif in the format url(*fileLocation*). The Web-page author also can set the background-color property in case the image is not found.

The **background-position** property (line 15) places the image on the page. The keywords **top**, **bottom**, **center**, **left** and **right** are used individually or in combination for vertical and horizontal positioning. An image can be positioned using lengths by specifying the horizontal length followed by the vertical length. For example, to position the image as horizontally centered (positioned at 50% of the distance across the screen) and 30 pixels from the top, use

```
background-position: 50% 30px;
```

The **background-repeat** property (line 16) controls the **tiling** of the background image. Tiling places multiple copies of the image next to each other to fill the background. Here, we set the tiling to **no-repeat** to display only one copy of the background image. The background-repeat property can be set to **repeat** (the default) to tile the image vertically and horizontally, **repeat-x** to tile the image only horizontally or **repeat-y** to tile the image only vertically.

The final property setting, **background-attachment: fixed** (line 17), fixes the image in the position specified by **background-position**. Scrolling the browser window will not move the image from its position. The default value, **scroll**, moves the image as the user scrolls through the document.

Line 21 indents the first line of text in the element by the specified amount, in this case **1em**. An author might use this property to create a Web page that reads more like a novel, in which the first line of every paragraph is indented.

Line 24 uses the **font-weight** property to specify the "boldness" of text. Possible values are **bold**, **normal** (the default), **bolder** (bolder than **bold** text) and **lighter** (lighter than **normal** text). Boldness also can be specified with multiples of 100, from 100 to 900 (e.g., 100, 200, ..., 900). Text specified as normal is equivalent to 400, and **bold** text is equivalent to 700. However, many systems do not have fonts that can scale with this level of precision, so using the values from 100 to 900 might not display the desired effect.

Another CSS property that formats text is the **font-style** property, which allows the developer to set text to **none**, **italic** or **oblique** (oblique will default to italic if the system does not support oblique text).

6.9 Element Dimensions

In addition to positioning elements, CSS rules can specify the actual dimensions of each page element. Figure 6.11 demonstrates how to set the dimensions of elements.

```
1
    <?xml version = "1.0"?>
    <!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1//EN"

Fig. 6.11 Element dimensions and text alignment. (Part 2 of 2.)

The inline style in line 22 illustrates how to set the **width** of an element on screen; here, we indicate that the div element should occupy 20% of the screen width. Most elements are left-aligned by default; however, this alignment can be altered to position the element elsewhere. The height of an element can be set similarly, using the **height** property. The height and width values also can be specified as relative or absolute lengths. For example

width: 10em

sets the element's width to be equal to 10 times the font size. Line 27 sets text in the element to be **center** aligned; other values for the text-align property include **left** and **right**.

One problem with setting both dimensions of an element is that the content inside the element can exceed the set boundaries, in which case the element is simply made large enough for all the content to fit. However, in line 32, we set the **overflow** property to **scroll**, a setting that adds scrollbars if the text overflows the boundaries.

6.10 Text Flow and the Box Model

A browser normally places text and elements on screen in the order in which they appear in the XHTML document. However, as we have seen with absolute positioning, it is possible to remove elements from the normal flow of text. **Floating** allows you to move an element to one side of the screen; other content in the document then flows around the floated element. In addition, each block-level element has a virtual box drawn around it, based on what is known as the **box model**. The properties of this box can be adjusted to control the amount of padding inside the element and the margins outside the element (Fig. 6.12).

Fig. 6.12 Floating elements, aligning text and setting box dimensions. (Part 2 of 2.)

In addition to text, whole elements can be **floated** to the left or right of content. This means that any nearby text will wrap around the floated element. For example, in lines 30-32 we float a div element to the right side of the screen. As you can see from the sample screen capture, the text from lines 34-39 flows cleanly to the left and underneath the div element.

The second property in line 30, margin, specifies the distance between the edge of the element and any other element on the page. When the browser renders elements using the box model, the content of each element is surrounded by **padding**, a **border** and a **margin** (Fig. 6.13).

Margins for individual sides of an element can be specified by using the properties margin-top, margin-right, margin-left and margin-bottom.

Lines 41–43 specify a div element that floats at the right side of the content. Property **padding** for the div element is set to .5em (half a line's height). **Padding** is the distance between the content inside an element and the element's border. Like the margin, the padding can be set for each side of the box, with padding-top, padding-right, padding-left and padding-bottom.

Fig. 6.13 Box model for block-level elements.

Lines 49–54 show that you can interrupt the flow of text around a floated element by setting the clear property to the same direction as that in which the element is floated right or left. Notice in the screen capture that the text from lines 45–47 flows to the left of the floated div element (lines 43–45), but the text from lines 49–54 does not. Setting the **clear** property to **all** interrupts the flow on both sides of the document.

Another property of every block-level element on screen is the border, which lies between the padding space and the margin space, and has numerous properties for adjusting its appearance, as shown in Fig. 6.14.

```

Fig. 6.14 Borders of block-level elements. (Part 2 of 2.)

In this example, we set three properties—**border-width**, **border-color** and **border-style**. The border-width property may be set to any valid CSS length or to the predefined value of **thin**, **medium** or **thick**. The border-color property sets the color. [*Note*: This property has different meanings for different style borders.]

As with padding and margins, each of the border properties may be set for an individual side of the box (e.g., border-top-style or border-left-color). A developer can assign more than one class to an XHTML element by using the class attribute, as shown in line 41.

The border-styles are none, hidden, dotted, dashed, solid, double, groove, ridge, inset and outset. Borders groove and ridge have opposite effects, as do inset and outset. Figure 6.15 illustrates these border styles.

6.11 User Style Sheets

Users can define their own **user style sheets** to format pages based on their preferences. For example, people with visual impairments may want to increase the page's text size. Web-page authors need to be careful not to inadvertently override user preferences with defined styles. This section discusses possible conflicts between **author styles** and **user styles**.

Figure 6.16 contains an author style. The font-size is set to 9pt for all tags that have class note applied to them.

🙆 Done

User style sheets are external style sheets. Figure 6.17 shows a user style sheet that sets the body's font-size to 20pt, color to yellow and background-color to #000080.

🖳 My Computer

Fig. 6.17 User style sheet.

User style sheets are not linked to a document; rather, they are set in the browser's options. To add a user style sheet in Internet Explorer 6, select **Internet Options...**, located in the **Tools** menu. In the **Internet Options** dialog (Fig. 6.18) that appears, click **Accessibility...**, check the **Format documents using my style sheet** checkbox, and type the location of the user style sheet. Internet Explorer 6 applies the user style sheet to any document it loads.

Fig. 6.19 User style sheet applied with pt measurement.

In this example, if users define their own font-size in a user style sheet, the author style has a higher precedence and overrides the user style. The 9pt font specified in the author style sheet overrides the 20pt font specified in the user style sheet. This small font may make pages difficult to read, especially for individuals with visual impairments. A developer can avoid this problem by using relative measurements (e.g., em or ex) instead of absolute measurements, such as pt. Figure 6.20 changes the font-size property to use a relative measurement (line 14) that does not override the user style set in Fig. 6.17. Instead, the font size displayed is relative to the one specified in the user style sheet. In this case, text enclosed in the tag displays as 20pt ,and tags that have class note applied to them are displayed in 15pt (.75 times 20pt).

Fig. 6.20 em measurement for text size. (Part 2 of 2.)

Figure 6.21 displays the Web page from Fig. 6.20 with the user style sheet from Fig. 6.16 applied. Note that the second line of text displayed is larger than the same line of text in Fig. 6.19.

6.12 Web Resources

www.w3.org/TR/css3-roadmap

The W3C *Cascading Style Sheets, Level 3* specification contains a list of all the CSS properties. The specification also provides helpful examples detailing the use of many of the properties.

www.ddj.com/webreview/style

This site has several charts of CSS properties, including a list stating which browsers support what attributes and to what extent.

tech.irt.org/articles/css.htm This site contains articles dealing with CSS.

SUMMARY

- The inline style allows a developer to declare a style for an individual element by using the style attribute in the element's start tag.
- Each CSS property is followed by a colon and the value of the attribute.
- The color property sets text color. Color names and hexadecimal codes may be used as the value.
- Styles that are placed in a style element apply to the entire document.
- style element attribute type specifies the MIME type (the specific encoding format) of the style sheet. Style sheets use text/css.
- Each rule body in a style sheet begins and ends with a curly brace ({ and }).
- Style class declarations are preceded by a period and are applied to elements of the specific class.
- The CSS rules in a style sheet use the same format as inline styles: The property is followed by a colon (:) and the value of that property. Multiple properties are separated by semicolons (;).
- The background-color attribute specifies the background color of the element.
- The font-family attribute names a specific font that should be displayed. Generic font families allow authors to specify a type of font instead of a specific font, in case a browser does not support a specific font. The font-size property specifies the size used to render the font.
- The class attribute applies a style class to an element.
- Pseudoclasses give the author access to content not specifically declared in the document. The hover pseudoclass is activated when the user moves the mouse cursor over an element.
- The text-decoration property applies decorations to text within an element, such as underline, overline, line-through and blink.
- To apply rules to multiple elements, separate the elements with commas in the style sheet.
- A pixel is a relative-length measurement: It varies in size based on screen resolution. Other relative lengths are em, ex and percentages.
- The other units of measurement available in CSS are absolute-length measurements—that is, units that do not vary in size. These units can be in (inches), cm (centimeters), mm (millimeters), pt (points; 1 pt=1/72 in) or pc (picas; 1 pc = 12 pt).
- External linking of style sheets can create a uniform look for a Web site; separate pages can all use the same styles. Modifying a single style sheet file makes changes to styles across an entire Web site.
- link's rel attribute specifies a relationship between two documents.
- The CSS position property allows absolute positioning, which provides greater control over where on a page elements reside. Specifying an element's position as absolute removes it from the normal flow of elements on the page and positions it according to distance from the top, left, right or bottom margin of its parent element.
- The z-index property allows a developer to layer overlapping elements. Elements that have higher z-index values are displayed in front of elements with lower z-index values.
- Unlike absolute positioning, relative positioning keeps elements in the general flow on the page and offsets them by the specified top, left, right or bottom value.
- Property background-image specifies the URL of the image, in the format url(*fileLocation*). The property background-position places the image on the page using the values top, bottom,

center, left and right individually or in combination for vertical and horizontal positioning. You can also position by using lengths.

- The background-repeat property controls the tiling of the background image. Setting the tiling to no-repeat displays one copy of the background image on screen. The background-repeat property can be set to repeat (the default) to tile the image vertically and horizontally, to repeat-x to tile the image only horizontally or to repeat-y to tile the image only vertically.
- The property setting background-attachment: fixed fixes the image in the position specified by background-position. Scrolling the browser window will not move the image from its set position. The default value, scroll, moves the image as the user scrolls the window.
- The text-indent property indents the first line of text in the element by the specified amount.
- The font-weight property specifies the "boldness" of text. Values besides bold and normal (the default) are bolder (bolder than bold text) and lighter (lighter than normal text). The value also may be justified using multiples of 100, from 100 to 900 (i.e., 100, 200, ..., 900). Text specified as normal is equivalent to 400, and bold text is equivalent to 700.
- The font-style property allows the developer to set text to none, italic or oblique (oblique will default to italic if the system does not have a separate font file for oblique text, which is normally the case).
- span is a generic grouping element; it does not apply any inherent formatting to its contents. Its main use is to apply styles or id attributes to a block of text. Element span is displayed inline (an inline element) with other text and with no line breaks. A similar element is the div element, which also applies no inherent styles, but is displayed on a separate line, with margins above and below (a block-level element).
- The dimensions of elements on a page can be set with CSS by using properties height and width.
- Text within an element can be centered using text-align; other values for the text-align property are left and right.
- One problem with setting both vertical and horizontal dimensions of an element is that the content inside the element might sometimes exceed the set boundaries, in which case the element must be made large enough for all the content to fit. However, a developer can set the overflow property to scroll; this setting adds scroll bars if the text overflows the boundaries set for it.
- Browsers normally place text and elements on screen in the order in which they appear in the XHTML file. Elements can be removed from the normal flow of text. Floating allows you to move an element to one side of the screen; other content in the document will then flow around the floated element.
- CSS uses a box model to render elements on screen. The content of each element is surrounded by padding, a border and margins. The properties of this box are easily adjusted.
- The margin property determines the distance between the element's edge and any outside text.
- Margins for individual sides of an element can be specified by using margin-top, margin-right, margin-left and margin-bottom.
- The padding property determines the distance between the content inside an element and the edge of the element. Padding also can be set for each side of the box by using padding-top, padding-right, padding-left and padding-bottom.
- A developer can interrupt the flow of text around a floated element by setting the clear property to the same direction in which the element is floated—right or left. Setting the clear property to all interrupts the flow on both sides of the document.
- The border of a block-level element lies between the padding space and the margin space and has numerous properties with which to adjust its appearance.

Chapter 6

- The border-width property may be set to any of the CSS lengths or to the predefined value of thin, medium or thick.
- The border-styles available are none, hidden, dotted, dashed, solid, double, groove, ridge, inset and outset.
- The border-color property sets the color used for the border.
- The class attribute allows more than one class to be assigned to an XHTML element by separating each class name from the next with a space.

SELF-REVIEW EXERCISES

- 6.1 Assume that the size of the base font on a system is 12 points.
 - a) How big is a 36-point font in ems?
 - b) How big is a 9-point font in ems?
 - c) How big is a 24-point font in picas?
 - d) How big is a 12-point font in inches?
 - e) How big is a 1-inch font in picas?
- **6.2** Fill in the blanks in the following statements:
 - a) Using the ______ element allows authors to use external style sheets in their pages.
 - b) To apply a CSS rule to more than one element at a time, separate the element names with a(n) _____.
 - c) Pixels are a(n) ______ -length measurement unit.
 - d) The _____ pseudoclass is activated when the user moves the mouse cursor over the specified element.
 - e) Setting the overflow property to _____ provides a mechanism for containing inner content without compromising specified box dimensions.
 - f) While ______ is a generic inline element that applies no inherent formatting and ______ is a generic block-level element that applies no inherent formatting.
 - g) Setting property background-repeat to ______ tiles the specified background-image vertically.
 - h) If you float an element, you can stop the flowing of text by using property _____
 - i) The _____ property allows you to indent the first line of text in an element.
 - j) Three components of the box model are the _____, ____ and _____.

ANSWERS TO SELF-REVIEW EXERCISES

6.1 a) 3 ems. b) 0.75 ems. c) 2 picas. d) 1/6 inch. e) 6 picas.

6.2 a) link. b) comma. c) relative. d) hover. e) scroll. f) span, div. g) y-repeat. h) clear. i) text-indent. j) padding, border, margin.

EXERCISES

6.3 Write a CSS rule that makes all text 1.5 times larger than the base font of the system and colors the text red.

6.4 Write a CSS rule that removes the underlines from all links inside list items (1i) and shifts all list items left by 3 ems.

6.5 Write a CSS rule that places a background image halfway down the page, tiling it horizon-tally. The image should remain in place when the user scrolls up or down.

6.6 Write a CSS rule that gives all h1 and h2 elements a padding of 0.5 ems, a grooved border style and a margin of 0.5 ems.

6.7 Write a CSS rule that changes the color of all elements containing attribute class = "greenMove" to green and shifts them down 25 pixels and right 15 pixels.

6.8 Write an XHTML document that shows the results of a color survey. The document should contain a form with radio buttons that allows users to vote for their favorite color. One of the colors should be selected as a default. The document should also contain a table showing various colors and the corresponding percentage of votes for each color. (Each row should be displayed in the color to which it is referring.) Use attributes to format width, border and cell spacing for the table.

6.9 Add an embedded style sheet to the XHTML document in Fig. 4.5. The style sheet should contain a rule that displays h1 elements in blue. In addition, create a rule that displays all links in blue without underlining them. When the mouse hovers over a link, change the link's background color to yellow.

6.10 Modify the style sheet in Fig. 6.4 by changing a:hover to a:hver and margin-left to margin left. Validate the style sheet using the CSS Validator. What happens?
